

1. **Electricity Bill Calculator**

Develop a webpage that accepts the number of electricity units consumed and the rate per unit. Calculate the total electricity charge, apply a discount for eligible customers, and display the final payable amount along with the average cost per unit.

2. **Library Fine Calculator**

Create a webpage that accepts the number of days a library book is overdue. Validate the entered value, determine the fine category based on the number of overdue days, and generate a countdown showing the remaining days until a specified maximum overdue period.

3. **Weekly Sales Analysis**

Store the sales amounts recorded by a shop for seven consecutive days in an array. Calculate the total sales, average daily sales, highest and lowest sales, and count the number of days on which sales exceeded a user-entered target amount.

4. **Device Information Dashboard**

Develop a webpage that displays information about the user's browsing environment using JavaScript browser objects. Display the browser language, operating system/platform, browser user-agent information, screen width, screen height, color depth, and whether the browser is currently online.

5. **Website Navigation Controller**

Create a webpage that accepts a URL from the user and displays its protocol, hostname, pathname, query parameters, and fragment identifier. Provide buttons to visit the entered URL, reload the current page, move to the previous page, and move to the next page in browser history.

6. **Responsive Layout Detector**

Develop a webpage that displays the current browser window's width and height. Based on the width, classify the window as **Mobile**, **Tablet**, or **Desktop**. The classification and dimensions must automatically update whenever the browser window is resized.
